Interactions and observables

In the study of string interactions, the ultimate goal will be the assignment of a probability for a certain process and the prediction of a physical cross section.

As outlined in Section 22, the computation of an observable cross section involves a series of steps:

1. Canonical representation of string diagram through moduli space
2. Compute scattering amplitude by means of conformal field theory
3. Convert scattering amplitude into a cross section

Loop amplitudes in string theory

In order to obtain accurate scattering amplitudes of processes, one needs to include contributions from loops in string diagrams.

These loops can be seen as contributions from the next higher order perturbation. Graphically we consider the following processes:

Ultraviolet divergence

Amplitudes from virtual processes as depicted before can lead to ultraviolet (UV) divergences in quantum field theory (QFT).

Whereas QFT must employ complex renormalizations to deal with these UV divergences, we do not encounter these problems in string theory.

4. Modular invariance of the amplitude

One-loop open strings

Before approaching the moduli space of tori, let's consider a one-loop open string with light-cone momentum p^+ . This will serve as an intuitive analogon.

The light-cone diagram is:

For fixed external momentum p^+ we find the two parameters: $\Delta T \in (0, \infty)$ and $p_1^+ \in (0, p^+)$.
→ The class of Riemann surfaces of this process has two moduli.

Canonical annulus

Use $w = \tau + i\sigma$ and apply conformal transformations:

1. Exponential map: $z = \exp\left[\frac{w}{2\alpha' p^+}\right]$
2. Linear fractional transformation: $\eta = \frac{1+iz}{1-iz}$
3. Canonical annulus: *A region in \mathbb{C} that is topologically an annulus can be mapped conformally to a canonical annulus*

Rectangular tori

In order to apply the concept of moduli spaces to a torus, we need to assure that a torus is indeed a Riemann surface.

Consider a rectangular region of \mathbb{C} . By applying the analytic identifications $z \sim z + L_1$ and $z \sim z + iL_2$ we obtain a torus. This shows that the region remains a Riemann surface.

Graphically:

Parametrisation

We have:

Rectangular torus

$$z \sim z + L_1 \text{ and } z \sim z + iL_2$$

By applying $z' = \frac{z}{L_1}$ the identifications become:

Torus parameter T

$$z' \sim z' + 1 \text{ and } z' \sim z' + iT \text{ with } T = \frac{L_2}{L_1}$$

Ultraviolet divergence

T is a parameter of the torus but does not yet define the moduli space, i.e. tori with different T can be conformally equivalent.

Consider the following series of conformal maps to a rectangular torus with $T < 1$:

Rectangular torus

Tori with T and $\frac{1}{T}$ are conformally equivalent

→ The moduli space can be chosen to be $T \in (0, 1]$ or $T \in [1, \infty)$

General tori

Rectangular tori represent only a subset off all conformally inequivalent tori. Let's construct a more general class of tori:

General construction of a torus Riemann surface

Choose $\omega_1, \omega_2 \in \mathbb{C}$ with $\text{Im}(\frac{\omega_1}{\omega_2}) > 0$.

A torus is obtained by the indentifications $z \sim z + \omega_1$ and $z \sim z + \omega_2$.

By scaling we obtain $z \sim z + 1$ and $z \sim z + \tau$ with $\tau = \frac{\omega_2}{\omega_1}$, $\text{Im}(\tau) > 0$.

→ Note that for $\tau = iT$ ($\Leftrightarrow \text{Re}(\tau) = 0$) we consider the rectangular torus.

Twisting the torus

Intuitively, if a cylinder is twisted and the end surfaces are connected, we expect a different torus.

Formally: Consider $\operatorname{Re}(\tau) \neq 0$ and a point $P = 0 = \tau$. We can reconstruct the rectangular *fundamental domain* by using the identification $z \sim z + 1$.

Graphically:

Twisting parameter

The point P is no longer identified with a point on the perpendicular. Indeed the degree of twisting is parametrised by $\theta = 2\pi \operatorname{Re}(\tau)$. How does the twisting angle θ affect the torus parameter τ ?

Consider the map $\tau \rightarrow \tau + 1$:

With the identification $z \sim z + 1$ we can conclude $\tau \sim \tau + 1$ and hence $\theta \sim \theta + 2\pi$.

Note:

The "twisting" does not correspond to actual torsion. It is the mere identification of the points P .

Moduli space I

So far we have established that $\text{Im}(\tau) > 0 \Leftrightarrow \tau \in \mathbb{H}$. However, the identification $\tau \sim \tau + 1$ implies that the space of inequivalent tori is smaller. Indeed:

Strip \mathcal{S}_0

$$\mathcal{S}_0 = \left\{ -\frac{1}{2} < \text{Re}(\tau) < \frac{1}{2}, \text{Im}(\tau) > 0 \right\}$$

Is \mathcal{S}_0 the moduli space of tori?

For rectangular tori we found that $T, \frac{1}{T}$ yield equivalent tori. Since $\tau = iT$ we have $\tau' = \frac{i}{T} = -\frac{1}{\tau}$.

Moduli space II

We have found two identifications with generators:

T-module transform

$$T\tau = \tau + 1$$

S-module transform

$$S\tau = -\frac{1}{\tau}$$

The corresponding fundamental domain should be a subset of \mathcal{S}_0 . Indeed, the S-module transform identifies points in $|\tau| < 1$ with points in $|\tau| > 1$.

Therefore we can postulate:

Fundamental domain \mathcal{F}_0

$$\mathcal{F}_0 = \left\{ -\frac{1}{2} < \operatorname{Re}(\tau) < \frac{1}{2}, \operatorname{Im}(\tau) > 0, |\tau| \geq 1 \text{ and } \operatorname{Re}(\tau) \geq 0 \text{ if } |\tau| = 1 \right\}$$

Modular group $PSL(2, \mathbb{Z})$

Consider a general linear fractional transformation $g \in G$:

$$g\tau = \frac{a\tau + b}{c\tau + d}, \quad \text{Im}(g\tau) = \frac{\text{Im}(\tau)}{|c\tau + d|^2} \quad (1)$$

with $a, b, c, d \in \mathbb{Z}$ and $ad - bc = 1$.

Equivalently we can use a matrix representation:

$$[g] = \begin{pmatrix} a & b \\ c & d \end{pmatrix}, \quad \det[g] = 1 \quad (2)$$

$\rightarrow g$ satisfies the group homomorphism $\phi : G \rightarrow G, [g_1 g_2] \mapsto [g_1][g_2]$.

We call G the modular group $PSL(2, \mathbb{Z})$.

In matrix notation we see that $[T] = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ and $[S] = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$

Proving \mathcal{F}_0

Claim

For all $\tau \in \mathbb{H}$ exists $g \in G'$ such that $g\tau \in \mathcal{F}_0$
 $\rightarrow \mathcal{F}_0$ contains exactly one copy of each inequivalent torus.

Step 1: For each τ there is $g \in G'$ such that $\text{Im}(g\tau)$ is largest.

Step 2: Show that $\tau' = T^n g\tau \in \mathcal{S}_0$ really is in $\bar{\mathcal{F}}_0$.

Step 3: Send $\tau \in \bar{\mathcal{F}}_0$ to $\tau \in \mathcal{F}_0$ via T- or S-transform.

4. Modular invariance of the amplitude

Compactified bosonic string

Consider one compactified coordinate $X \sim X + 2\pi r$. In a free field theory the action can be written as $S = \frac{1}{2\pi} \int \partial X \partial \bar{X}$.

For a compactified closed string a Euclidean path integral yields the following expression for the partition function:

$$Z(r) = \int e^{-S} = \frac{1}{|\eta|^2} \sum_{m,n} q^{\frac{1}{2}p_L^2} \bar{q}^{\frac{1}{2}p_R^2} \quad (3)$$

where

$$p_L = \frac{m}{2r} + nr \text{ and } p_R = \frac{m}{2r} - nr \quad (4)$$

Return to Minkowski space

For $r \rightarrow \infty$ we get continuous momenta $p_L = p_R = \frac{m}{2r}$ and with $q = e^{2\pi i \tau}$ we can transform back to Minkowski space:

$$\begin{aligned} Z(r) &= \frac{1}{|\eta|^2} \int_{-\infty}^{\infty} dk q^{\frac{1}{2}k^2} \bar{q}^{\frac{1}{2}} \\ &= \frac{1}{|\eta|^2} \int_{-\infty}^{\infty} dk e^{2\pi i \frac{1}{2}k^2 \tau} e^{-2\pi i \frac{1}{2}k^2 \bar{\tau}} \\ &= \frac{1}{|\eta|^2} \int_{-\infty}^{\infty} dk e^{2\pi i \frac{1}{2}k^2 2i \operatorname{Im}\{\tau\}} \\ &= \frac{1}{|\eta|^2} \int_{-\infty}^{\infty} dk e^{-2\pi k^2 \operatorname{Im}\{\tau\}} \\ &\propto \frac{1}{|\eta|^2} \frac{1}{\operatorname{Im}(\tau)^{\frac{1}{2}}} \end{aligned}$$

T-duality

Consider again the momentum and winding for the compactified string:

$$p = \frac{m}{r} \text{ and } w = nr \quad (5)$$

We see that if we interchange $m \rightarrow n$ and $\frac{1}{r} \rightarrow r$, we interchange the meaning of winding and momentum.

This change however leaves the partition function invariant and we can conclude T-duality for the compactified closed string partition function.

Partition function via state trace

In quantum statistics:

$$Z = \text{Tr}(e^{-\beta H}) \propto \sum_{\Phi} \langle \Phi | H | \Phi \rangle \quad (6)$$

The trace should run over all states of the torus. This means we need to find a propagator which propagates through all configurations in τ and σ .

Consider the state trace for a harmonic oscillator with number operators N_L, N_R in 24 transverse dimensions:

$$\text{Tr}(\bar{q}^{N_L-1} q^{N_R-1}) = (q\bar{q})^{-1} \prod_{n=1}^{\infty} (1 - \bar{q}^n)^{-24} (1 - q^n)^{-24} = \frac{1}{|\eta(\tau)|^{48}} \quad (7)$$

The *Dedekind eta function* is defined as:

$$\eta(\tau) = q^{\frac{1}{24}} \prod_{n=1}^{\infty} (1 - q^n) \quad (8)$$

Therefore we get:

$$(q\bar{q})^{-\frac{1}{24}} \text{Tr}\left(q^{L_0} \bar{q}^{\bar{L}_0}\right) = \frac{1}{|\eta|^2} \quad (9)$$

The Dedekind eta function satisfies:

$$\eta(\tau + 1) = e^{i\frac{\pi}{12}} \eta(\tau) \text{ and } \eta\left(-\frac{1}{\tau}\right) = \sqrt{-i\tau} \eta(\tau) \quad (10)$$

Hamiltonian interpretation

In light-cone gauge we have:

$$H_{l.c.} = \frac{\alpha'}{2} p^I p^I + N^\perp + \bar{N}^\perp - 2 \quad (11)$$

and

$$P_{l.c.} = N^\perp - \bar{N}^\perp \quad (12)$$

The general expression for the oscillator trace becomes (using $\tau = \tau_1 + i\tau_2$):

$$\begin{aligned} &= \text{Tr} \left(e^{-2\pi\tau_2(N^\perp + \bar{N}^\perp - 2)} e^{2\pi i\tau_1(N^\perp - \bar{N}^\perp)} \right) \\ &= e^{\pi\alpha'\tau_2(p^I)^2} \text{Tr} \left(e^{-2\pi\tau_2 H_{l.c.}} e^{-2\pi i\tau_1 P_{l.c.}} \right) \end{aligned}$$

We can therefore conclude:

$$Z(\tau, \bar{\tau}) \propto \text{Tr} \left(e^{-2\pi\tau_2 H_{l.c.}} e^{-2\pi i\tau_1 P_{l.c.}} \right) \quad (13)$$

With a few more transformations we can obtain an expression for the partition function w.r.t. the Virasoro operators:

$$Z(\tau, \bar{\tau}) = \text{Tr} \left(q^{L_0 - \frac{c}{24}} \bar{q}^{\bar{L}_0 - \frac{\bar{c}}{24}} \right) \quad (14)$$

Is this a reasonable result? Two hints:

I:

$$\mathrm{Tr}(q^{L_0}) \propto \mathrm{Tr}\left(q^{\sum_{n=1}^{\infty} \alpha_{-n} \alpha_n}\right) = \prod_{n=1}^{\infty} (1 + q^n + q^{2n} + \dots) = \prod_{n=1}^{\infty} \frac{1}{1 - q^n} \quad (15)$$

This is the partition function of a boson from the Bose-Einstein distribution.

II:

$$\begin{aligned} q^{L_0} \bar{q}^{\bar{L}_0} &= e^{2\pi i(\tau_1 + i\tau_2)L_0} e^{-2\pi i(\tau_1 - i\tau_2)\bar{L}_0} \\ &= e^{2\pi i\tau_1(L_0 - \bar{L}_0)} e^{-2\pi\tau_2(L_0 + \bar{L}_0)} \end{aligned}$$

We can interpret $L_0 - \bar{L}_0$ as the momentum P which generates translation in σ . Similarly $L_0 + \bar{L}_0$ can be seen as Hamiltonian H which generates τ translation.

The propagator has then the interpretation of a τ and σ sweep.

Outline

1. Motivation

4. Modular invariance of the amplitude

The amplitude

The correctly normalized one-loop vacuum amplitude reads:

$$A_0^{g=1} = \frac{V_{26}}{l_s^{26}} \int_{\mathcal{F}_0} \frac{d^2\tau}{4(\text{Im}(\tau))^2} Z(\tau, \bar{\tau}) \quad (16)$$

This amplitude carries the correct physical intuition: each possible form of a one-loop interaction is parametrised by τ . To get a probability measure for a process we therefore need to weight every $\tau \in \mathcal{F}_0$ with the partition function $Z(\tau, \bar{\tau})$

With the found partition function for the 24-dimensional transverse coordinate space we have:

$$A_0^{g=1} = V_{26} \int_{\mathcal{F}_0} \frac{d^2\tau}{16\pi^2 \alpha' \tau_2^2} \int \frac{d^{24}p}{(2\pi)^{24}} \text{Tr} \left(e^{-2\pi\tau_2 H_{l.c.}} e^{-2\pi i \tau_1 P_{l.c.}} \right) \quad (17)$$

This expression makes sense when we link it to the construction of the moduli space:

Consider $\tau_1 = 0$. In this case τ_2 plays the role of a Euclidean time. We know that $\tau_1 = 0$ corresponds to a rectangular torus.

The partition function counts the number of states propagating around the torus in τ_2 direction and weights them with $e^{-2\pi\tau_2 H_{l.c.}}$.

Now consider a cylinder with length τ_2 whose ends are identified. We can twist the ends by the twist angle $\theta = 2\pi\tau_1$. This twist is then induced by $P_{l.c.}$.

Modular invariance

The proposed amplitude is only valid if equivalent tori, i.e. equivalent interactions, result in the same amplitude.

We therefore need to have invariance under T- and S-module transforms.

The integration domain \mathcal{F}_0 is by definition modular invariant.

Consider a general modular transformation g on the measure:

$$\begin{aligned} d(g\tau) &= \left[\frac{a(c\tau + d) - (a\tau + b)c}{(c\tau + d)^2} \right] d\tau \\ &= \left[\frac{ad - bc}{(c\tau + d)^2} \right] d\tau \end{aligned}$$

So $d^2\tau \rightarrow |c\tau + d|^{-4} d^2\tau$

Also: $\text{Im}(\tau) \rightarrow |c\tau + d|^{-2} \text{Im}(\tau)$

Therefore the measure transforms like:

$$\frac{d^2\tau}{\text{Im}(\tau)^2} \rightarrow \frac{|c\tau + d|^{-4} d^2\tau}{(|c\tau + d|^{-2} \text{Im}(\tau))^2} = \frac{d^2\tau}{\text{Im}(\tau)^2} \quad (18)$$

Since the modulus of the eta function stays invariant under T- or S-module transforms, we can conclude that the partition function is also modular invariant.

This makes the whole amplitude modular invariant.
